Component:	Case Management			

Description

Implementation of the form layout and renderer in order to promote dynamic forms (and prevent customization of the desktop version to country's specific needs).

Initial implementation:

Form structure

A form is composed of the following structure:

Form -> Sections -> Controls/Text

So a class model must be implemented in order to host this structure. In order to get flexibility, the form structure must be stored in a XML file format. Classes to parse the XML structure must be implemented.

Form renderer

Library responsable for

- generating the form UI through a form definition stored in a form structure.
- Bind values of the data model to the form UI;
- Validation of the form according to the validation rules;

History
